September 16, 2008

- AIRS/IASI/CrIS promise to give us a 20+ year hyperspectral time-series of climate
- How well can we tie together the AIRS and IASI records? (AIRS won't be around for CLARREO.)
- RTA performance and issues for climate
- A new method for deriving spectroscopy from radiances??

- AIRS stability is $<0.01\text{K/year}$, probably sufficient for climate trends. IASI appears to have very good stability as well.
- Spectroscopy is only good to, at the very best, $0.1\text{-}0.2\text{K}$
- Climate studies using retrievals require consistent RTA's, making intercomparisons among groups very difficult
- Retrievals sensitive to prior (assimilation), and cloud clearing performance (limited in troposphere in mid-, higher-latitudes)
- At present, I do not have a statistical set of high-quality coincident sondes measurements for IASI. Do they exist?
- IASI and AIRS agree far better than the spectroscopy

Overview

RTA Status

IASI vs AIRS

Secant Bias

Trends

- AIRS V5 RTA: tuned, older spectroscopy
- Tuning used ARM TWP (tested with ARM SGP) RS-90, Frost-Point hygrometer coincident radiosondes
- This work:
 - V6 RTAs
 - HITRAN 2004+ (ozone, water are main changes)
 - Presently “untuned”, giving poorer performance, but our baseline
 - IASI clearly needs same tuning, but for different SRFs
- Biases shown are larger than used in AIRS V5 system. NOAA/NESDIS is using V6 RTA for IASI.
- AIRS frequency calibration on per-granule basis complete. Analysis not yet included in these results. Errors $<0.05\text{K}$ and mostly random.

IASI vs AIRS

Secant Bias

Trends

Use two independent techniques to intercompare IASI and AIRS radiance.

- 1 Simultaneous nadir overpasses (SNOs).
 - IASI and AIRS in different orbits, so tight time/space overlaps limits SNOs to ± 73.8 degrees
 - SNOs are relatively cold spectra, esp. in window regions.
- 2 Double-differences of sensor biases versus model (ECMWF)
 - RTA calculations using ECMWF model data can reproduce radiances for clear ocean-only FOVs to within $\sim 0.2 - 1.0\text{K}$ in many channels.
 - Double differences;
 $(\text{obs} - \text{cal}(\text{ECMWF}))_{\text{IASI}} - (\text{obs} - \text{cal}(\text{ECMWF}))_{\text{AIRS}}$
removes most inaccuracies in the RTA and ECMWF
 - Essentially ECMWF used to interpolate over the 4 hour time difference in the orbits

- Data from May 2007 to Feb. 2008
- Matchup thresholds are $\Delta t = 2$ minutes, $\Delta d = 30$ km, from nadir orbit crossing point
- This resulted in 284 SNO's each containing 3-4 IASI FOVs and 6-8 AIRS FOVs. Standard deviations of these individual measurements are made and propagated into means over the 284 SNO's.
- Except for shortwave, statistical errors in AIRS-IASI BT differences are roughly equivalent to the mean differences. SW statistics are not as good.
- Cross-convolve each radiance with other instrument's SRF

IASI/AIRS RTA

L. Strow
UMBC

Overview

RTA Status

IASI vs AIRS

Secant Bias

Trends

- Observations are clear ocean FOVs for month of July 2007 for latitude range of ± 25 degrees, where ECMWF is very good, diurnal variations smallest
- Essential that the RTA for both instruments has identical spectroscopy.
- Avoid channels with high sensitivity above 70 mbar
- Added correction for diurnal change in SST (not done in ECMWF)
- Cross-convolve each radiance with other instrument's SRF
- In doing this work, we found a small, sampling error in our IASI RTA production that can give $\sim 0.2\text{K}$ errors that vary pseudo-randomly with frequency.

- Two approaches to IASI, AIRS inter-calibration show similar results
- Frequency calibration of AIRS not done here, will be at the 0.05K level or lower, will be ready soon for implementation
- Small IASI RTA errors limiting result, esp. standard deviations. We will build a new IASI RTA to fix this.
- Results suggest we are hitting the 0.1K level. Agreement between two approaches is getting below 0.1K
- Variability with AIRS arrays seen, suggesting adjustments may be warranted.
- More statistics needed.

- Empirical corrections used average biases
- Spectroscopy, constituent abundance errors will vary with viewing angle/secant
- Assume ECMWF errors do not depend on secant angle
- Fit $dbias = offset + slope \times \Delta secant$; *offset* very small
- If assume $bias = (inst_bias, model_bias) + slope \times secant$ can use above fit to determine slope, and then solve for (inst_bias,model_bias)
- Still need atmospheric constituent amount/profile to get spectroscopy

Fit Results: Slope of dbias/dsec

Secant varies from 1 to 1.37

IASI/AIRS RTA

L. Strow
UMBC

Overview

RTA Status

IASI vs AIRS

Secant Bias

Trends

- RTA accuracy might be $\sim 0.2\text{K}$. Spectroscopy error from secant variation close to Slide 7 results from coincident sondes
- IASI and AIRS agree to better than 0.1K . Radiometric errors may depend on observed $B(T)$. AIRS hotter by 0.1K ?
- Further progress on Std. Dev. requires new IASI RTA, attention to AIRS frequency calibration
- Extremely small trends seen in clear FOV data, combination of CO_2 , temperature, and H_2O
- Water trends probably not useful - clear FOVs only introduces sampling errors.
